

Competitor name	Strengths	Weaknesses	Competition values	Opportunities
Wildfire Analyst Pocket (Technosylva, US)	You get results in seconds on a 3D map, and it fills in fuel and weather data for you. Fire agencies use it, and it runs on US Forest Service fire science.	Its fuel data (LANDFIRE) stops at the US border and it uses US fire equations, so it doesn't fit Canadian forests. It's also made for trained fire crews, not the public.	Fast, accurate answers in the field for fire professionals.	Nothing like it exists for Canada. We can offer the same tap-and-see idea with Canadian data and equations, explained so the public can follow it.
FBP Go (Government of British Columbia)	It's official and free, and it runs Canada's own fire behaviour equations on a phone. It covers 18 Canadian fuel types and doesn't collect any user data.	There's no map, no live weather and no terrain data. You type every input by hand, including fuel codes that only fire staff would know, and it's designed mainly for iPad.	Being an official calculator that fire personnel can trust.	We can fill the inputs in automatically and put the results on a map. FBP Go is also handy for checking that our math is right.
REDapp (supported by the Canadian Interagency Forest Fire Centre)	Fire agencies across Canada back it. It takes less training than other professional fire models, and it connects fire weather ratings to how a fire would actually behave.	It's a calculator for agency staff, not a map, and nobody designed it with the public in mind.	A shared standard that Canadian fire agencies all use.	A map-first version that anyone can pick up without training, built on the same Canadian science.

WindNinja (US Forest Service)	It adjusts forecast wind for hills, ridges and valleys, and it's free and open source. It gets used on nearly every large US wildfire (about 7 million runs a year) and a lot of other fire tools build it in.	It only handles wind, not fire behaviour, and it's an expert tool that takes some setup.	Open, accurate science that other tools can build on.	Because it's open source, we could plug it in later so the app handles mountain areas like Banff better.
CWFIS website (Natural Resources Canada)	This is the official national source. It has fire weather maps every day of the year, active fires and fire perimeters in season, a fire history explorer, and it's all free open data.	The maps are national overviews written for technical users. They don't answer "what would a fire do at my spot," and you can't save places or get alerts.	Being the trusted, open source of national fire data.	We'd build on their data instead of competing with it, and add a personal, plain-language layer on top.
